The objectives of the study

1. Assess the noise effects of the opening of the new road through the comparison between the two scenarios (before and after 1997)
2. Analyse how the traffic flow changes affected the population noise exposure

... with the aim to give helpful methodology to assess further and future measures in order to reduce the negative effects of traffic

Noise analysis of the area of interest for the two scenarios

Noise mapping:

- Digital model construction
- Traffic flow data
- NMPB-Routes-96 Algorithm
- IMMI software

**Costa di Sorreley
Tunnel**

SS27 National Road

Noise analysis of the area of interest for the two scenarios

Model validation through noise and traffic flow measurements
(long time and short time)

Costa di Sorreley
Tunnel

SS27 National Road

Noise analysis of the area of interest for the two scenarios

The calculation was carried out for the area around the road sources included in a band of 150 meters from the roads

Noise indicators

European Environmental Noise Directive 2002/49/EC

Italian Legislation, Dlgs 19/08/2005, n.194

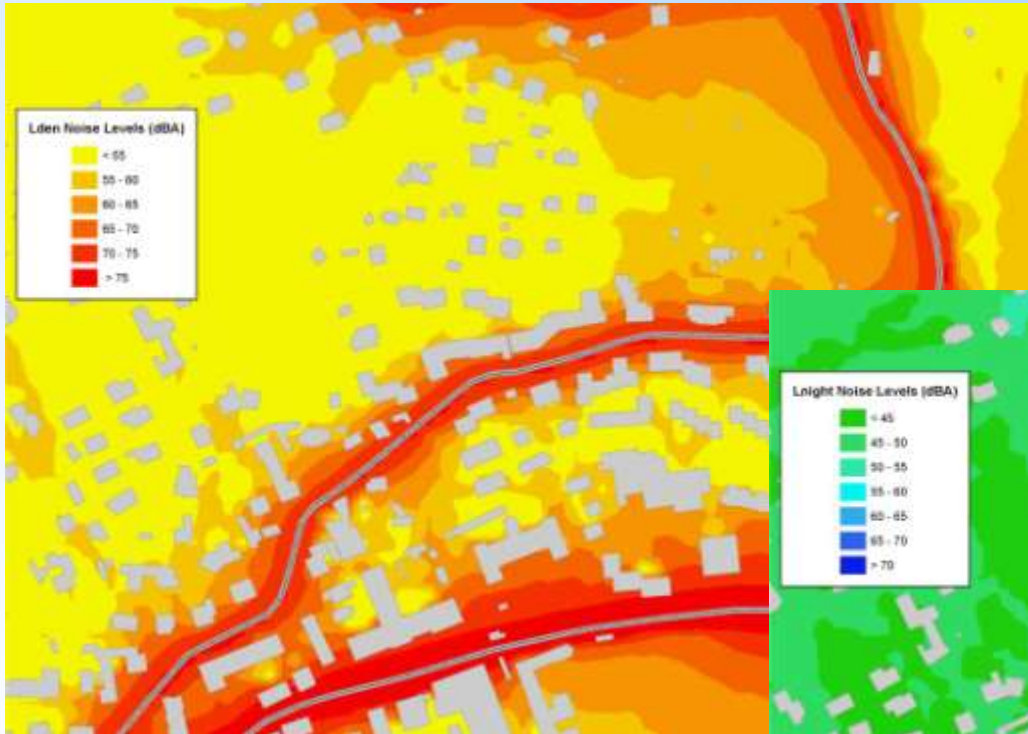

$$L_{den} = 10 \cdot \text{Log} \left[\frac{1}{24} \left(14 \cdot 10^{\frac{L_{day}}{10}} + 2 \cdot 10^{\frac{L_{evening} + 5}{10}} + 8 \cdot 10^{\frac{L_{night} + 10}{10}} \right) \right]$$

Where :
Daytime level = 06-20
Eveningtime level = 20-22
Nighttime level = 22-06

L_{night} Evaluated from 22:00 to 6:00

First result: noise mapping

Lden

Lnight

Population exposure

- the analysis took into account only resident inhabitants
- the number of inhabitants of each building was supplied by the public administration of the town of Aosta

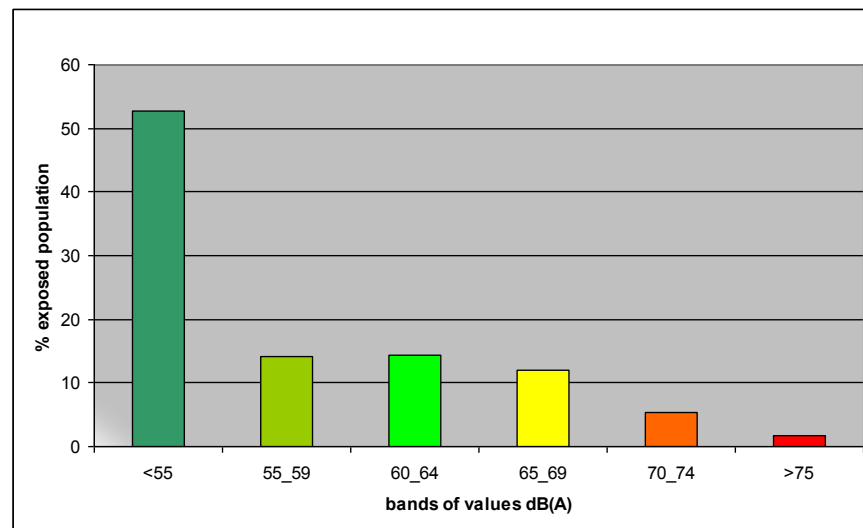

Two methods were followed to refer the number of inhabitants for each building to sound levels

- referring all the dwelling inhabitants to the most exposed façade level
(END 2002/49/EC method)
- assigning the inhabitants proportionally to the dwelling façades
(German assessment VBEB method)

Second result: population exposure with reference to two different evaluation methodologies

- referring all the dwellings inhabitants to the most exposed façade level

- assigning the inhabitants proportionally to the façades

Second result: population exposure with reference to two different evaluation methodologies

About the difference between the two methods:

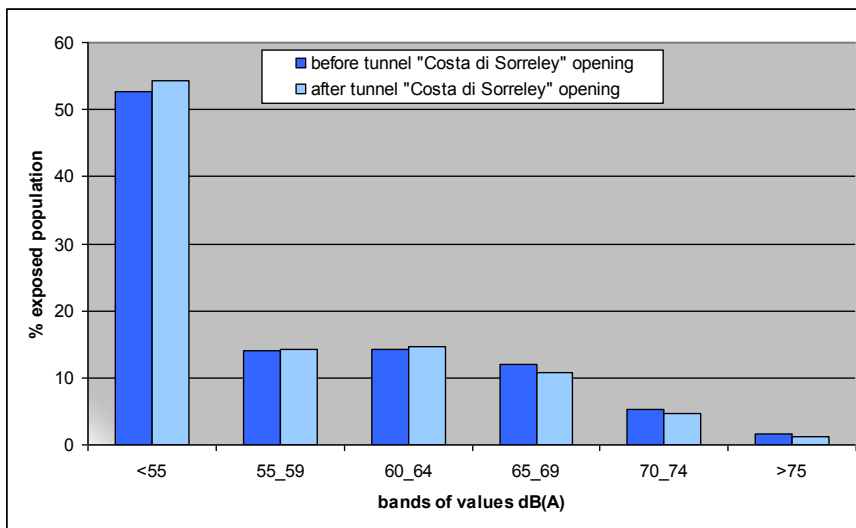

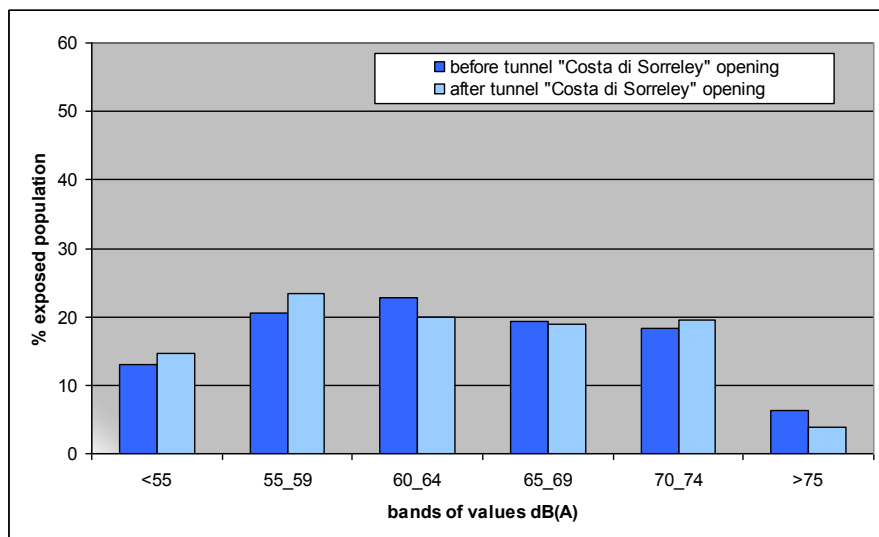

referring all the inhabitants to the level of the most exposed façade is in agreement with caution and prudence principles, but it could lead to overestimate the noise exposure and to adopt excessive abatement measures

Further result: comparison between two scenarios

- referring all the dwellings inhabitants to the most exposed façade level

- assigning the inhabitants proportionally to the façades

Final considerations

Noise level maps representing existing or predicted noise levels are not the final result of an analysis.

They are useful elements for action planning.

The cross between noise maps and population distribution is a fundamental step.

The result is the population noise exposure evaluation.

During the population noise exposure evaluation, in order to develop traffic infrastructures planning, it is necessary to carry out very attentively each of those steps

Thank you very much !
